Anju Thomas

**Ericsson** 

### AGENDA

- OVS Bond Modes Pros & Cons
- Limitations with current design
- Proposed optimization
- Test topology & Test results
- New CLI
- Summary

### **BOND MODES**

- Balance-SLB (Source Load Balance)
  - Uses source mac address and VLAN hash to identify member link.
  - Better packet throughput as no additional recirculation required.
  - Poor load balancing when using overlay tunnels like VxLAN.

#### Balance-TCP

- Uses 5-tuple hash to identify member link.
- Better distribution and load balancing.
- Low packet throughput due to additional recirculation of packet.

### **CURRENT DESIGN**

Uses hash() & recirc() actions

Recirculation of packets reduces the packet throughput.

• Post recirculation flows (a.k.a. pr-rules) occupy EMC cache entries.

Unique recirculation id for each bond port.

#### EXAMPLE DPCLS FLOWS

With 8 IP-UDP flows (with random UDP source port):

$$\label{localization} \begin{split} &\text{recirc\_id(0),in\_port(7),packet\_type(ns=0,id=0),eth(src=02:00:00:02:14:01,dst=0c:c4:7a:58:f0:2b),eth\_type(0x0800),ipv4(frag=no),actions: \\ &\text{hash\_l4(0)),recirc(0x1)} \end{split}$$

#### Post-recirculation flows (pr-rules):

 $recirc\_id(0x1), dp\_hash(0xf8e02b7e/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:2 \\ recirc\_id(0x1), dp\_hash(0xb236c260/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x7d89eb18/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0xa78d75df/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:2 \\ recirc\_id(0x1), dp\_hash(0xb58d846f/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x24534406/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x3cf32550/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x3cf32550/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x3cf32550/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x3cf32550/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x3cf32550/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x3cf32550/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x3cf32550/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x3cf32550/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x3cf32550/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x3cf32550/0xff), in\_port(7), packet\_type(ns=0, id=0), eth\_type(0x0800), ipv4(frag=no), actions:1 \\ recirc\_id(0x1), dp\_hash(0x3cf32550/0xff), in\_port(0x3cf32550$ 

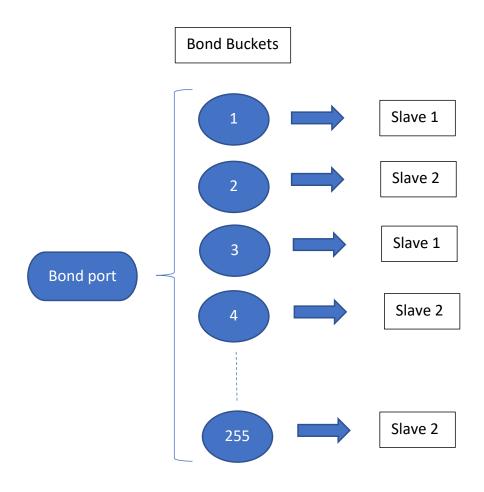

• Up to 255 unique pr-rules matching each possible hash (8-bits) for bond-port.

09-Dec-19 5

### PROPOSED DESIGN

- Bond buckets
  - Pre-create 255 buckets (equivalent to 255 pr-rules).
  - Bucket indexed using RSS hash (if available) or 5-tuple hash.
  - Statistics maintained at bucket level for load balancing.
- Bond-id used to identify bond port.
- Each bond port has its own set of bond buckets.
- Each PMD maintains bond cache with mapping of bond buckets to slaves.

### NEW DATAPATH ACTION

- lb\_output(bond, <bond-id>)
  - Replaces hash() and recirc() actions for balance-tcp mode.
  - Bond id is same as recirculation id
- Example datapath flow for packets from vm-port to bond-port :

```
in_port(7),packet_type(ns=0,id=0),eth(src=02:00:00:02:14:01,dst=0c:c4:7a:58:f0:2b), eth_type(0x0800),ipv4(frag=no), actions: lb_output(bond,1)
```

Only one dpcls flow entry irrespective of hash.

### LOAD BALANCING

- Each bucket maintain packets and bytes count.
- Core load balancing logic (ofproto) remains intact.
- For redistribution modify buckets to use different slave id.
- Change in bucket mapping needs PMD to refresh bond cache.

#### bond-id 1:

bucket 0 – slave 2

bucket 1 – slave 1

bucket 2 – slave 2

bucket 3 – slave 1

#### bond-id 1:

bucket 0 - slave 1

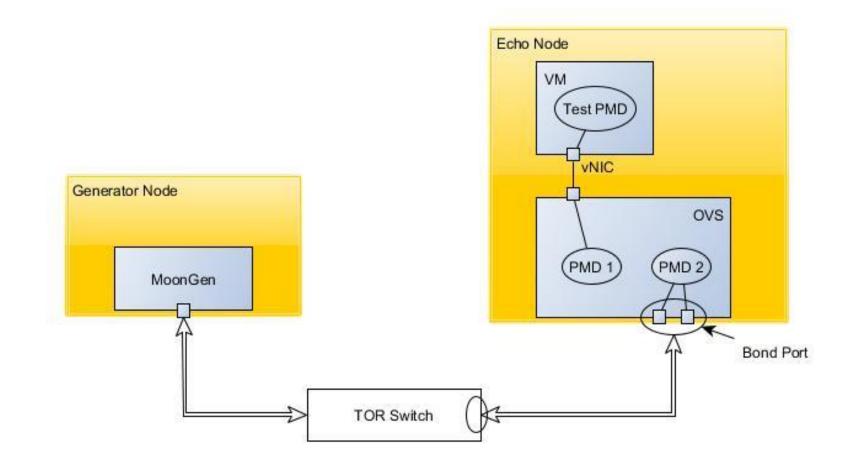

bucket 1 – slave 1

bucket 2 – slave 2

bucket 3 – slave 2

## **TEST TOPOLOGY**

### TEST PARAMETERS

- Phy -> VM -> Phy test (PVP)
- Loss profile < 10 ppm
- Packet size 64 bytes, UDP
- Multiple unique packet streams
- 2 PMDs

# TEST RESULTS

# of packet streams	OVS Master (Mpps)	OVS Master + Optimization (Mpps)	% Improvement
1	4.47	5.73	28%
10	4.17	5.35	28%
1000	3.41	5.25	53%
10000	2.53	4.57	80%
100000	2.33	4.27	83%
500000	2.33	4.27	83%

### **NEW CLI**

- To enable/disable:
  - ovs-vsctl set port <bond port> other\_config:lb-output-action=<true | false>
  - By-default it is false.
- To dump bond cache in datapath:
  - ovs-appctl dpif-netdev/dp-bond-show [dp]
- To check if bond port is using new action:
  - ovs-appctl bond/show

09-Dec-19 12

#### **SUMMARY**

- Balance-TCP bond mode provides better load distribution due to 5-tuple hash.
- Use of bond buckets eliminates recirculation of packets for bond member selection.
- Supported in 'netdev' datapath only. Kernel datapath will continue to use existing actions.
- Patch-set in the mailing list for review.
